HIGGS BOSON MASS IN THE MINIMAL UNIFIED SUBQUARK MODEL

In the minimal unified subquark model of all fundamental particles and forces, the mass of the Higgs boson in the standard model of electroweak interactions ($m_H$) is predicted to be about $2m_W \sqrt{6}/3$ (where $m_W$ is the mass of the charged weak boson) so that $m_H = 131$ GeV for $m_W = 80.4$ GeV, to which the experimental values of 125-126 GeV recently found by the ATLAS and CMS Collaborations at the LHC are very close.

Key words: elementary particles, Higgs-boson.

What most of us can expect to find in high energy experiments at the Large Hadron Collider is the Higgs boson (H), which is the only fundamental particle that has not yet been found in the standard model of electroweak interactions [1]. In the united composite model of all fundamental particles and forces [2], the mass of the Higgs boson has been predicted in the following three ways.

In general, in composite models of the Nambu-Jona-Lasinio type [3], the Higgs boson appears as a composite state of fermion-antifermion pairs with the mass twice as much as the fermion mass. The united subquark model of the Nambu-Jona-Lasinio type [4] has predicted the following two sum rules:

$$m_W = \left[3 \left( m_{w_1}^2 + m_{w_2}^2 \right) / 2 \right]^{1/2}$$

and

$$m_H = 2 \left[ \left( m_{w_1}^4 + m_{w_2}^4 \right) / \left( m_{w_1}^2 + m_{w_2}^2 \right) \right]^{1/2}$$

where $m_{w_i}$ and $m_{w_2}$ are the masses of the weak-iso-doublet spinor subquarks called "wakems" standing for weak and electromagnetic ($w_i$ for $i = 1,2$) while $m_W$ and $m_H$ are the masses of the charged weak boson (W) and physical Higgs boson in the standard model, respectively. By combining these sum rules, the following relation has been obtained if $m_{w_1} = m_{w_2}$:

$$m_w : m_W : m_H = 1 : \sqrt{3} : 2.$$  

From this relation, the wakem and Higgs boson masses have been predicted as

$$m_w = m_W / \sqrt{3} = 46.4 \text{ GeV}$$

and

$$m_H = 2m_W / \sqrt{3} = 92.8 \text{ GeV}$$

for $m_W = 80.4$ GeV [5]. On the other hand, if $m_{w_1} / m_{w_2} = 0$ or $m_{w_2} / m_{w_1} = 0$ but not both, the other relation can be obtained:

$$m_w : m_W : m_H = 1 : \sqrt{3/2} : 2.$$  

From this relation, the non-vanishing wakem and Higgs boson masses can be predicted as

$$m_w = m_W \sqrt{3/2} = 65.6 \text{ GeV}$$

and

$$m_H = 2m_W / \sqrt{3/2} = 131 \text{ GeV}$$
for $m_W = 80.4$ GeV [5]. More generally, from the two sum rules, the Higgs boson mass can be bounded as

$$92.8 \text{ GeV} \leq m_H \leq 131 \text{ GeV}$$

In the unified quark-lepton model of the Nambu-Jona-Lasinio type [4], the following two sum rules for $m_W$ and $m_H$ have been predicted:

$$m_W = (3 < m_{ql}^2 >)^{1/2}$$

and

$$m_H = 2 \left( \frac{\Sigma m_{ql}^4}{\Sigma m_{ql}^2} \right)^{1/2},$$

where $m_{ql}$'s are the quark and lepton masses and $<>$ denotes the average value for all the quarks and leptons. If there exist only three generations of quarks and leptons, these sum rules completely determine the top quark and Higgs boson masses [6] as

$$m_t \equiv (2\sqrt{6}/3) m_W = 131 \text{ GeV}$$

and

$$m_H \equiv 2 m_t \equiv 2(4\sqrt{6}/3) m_W = 263 \text{ GeV}.$$  

Furthermore, triplicity of hadrons, quarks, and subquarks [7] tells us that these sum rules can be further extended to the approximate sum rules of

$$m_W \equiv (3 < m_{ql}^2 >)^{1/2}$$

and

$$m_H \equiv 2 \left( \frac{\Sigma m_{ql}^4}{\Sigma m_{ql}^2} \right)^{1/2},$$

where $m_{ql}$'s are the "canonical baryon" and lepton masses and $<>$ denotes the average value for all the canonical baryons and leptons. The "canonical baryon" means either one of $p,n$ and other ground-state baryons of spin 1/2 and weak-isospin 1/2 consisting of a quark heavier than the u and d quarks and a scalar and isoscalar diquark made of u and d quarks. If there exist only three generations of quarks and leptons, these sum rules completely determine the masses of the canonical topped baryon, $T$, and the Higgs scalar as

$$m_T \equiv 2 m_w = 161 \text{ GeV}$$

and

$$m_H \equiv 2 m_T \equiv 4 m_w = 322 \text{ GeV}.$$  

Therefore, if the Higgs boson is found with the mass between 92.8 GeV and 131 GeV, it looks like a composite state of subquark-antisubquark pairs. If it is found heavier with $m_H$ around 263 GeV or even 322 GeV, it can be taken as a bound state of $t \bar{t}$ ("toponium") or $T \bar{T}$ ("topped-baryonium"), respectively. If it is found with the mass lying between these typical masses, it may be taken as a mixture of subquark-antisubquark pairs and quark-antiquark pairs, etc.

Very recently, the ATLAS and CMS Collaboration experiments at the CERN Large Hadron Collider have almost excluded the two ranges for the Higgs boson mass: the one lower than 114 GeV and the other between 141 GeV and 476 GeV [8,9], which disagrees with both the prediction in the unified quark-lepton model of the Nambu-Jona-Lasinio type [4] and that in the unified baryon-lepton model of the Nambu-Jona-Lasinio type [7]. Instead, the prediction in the unified subquark model [4] ($92.8 \text{ GeV} \leq m_H \leq 131 \text{ GeV}$) shows a right ballpark on which the mass of the Higgs boson in the standard model should land. Moreover, the fact that the experimental values of $m_H = 125-126$ GeV recently found by the ATLAS and CMS Collaborations are very close to the predicted one of $m_H = 2\sqrt{6} m_W / 3 = 131 \text{ GeV}$ seems to strongly suggest that either $m_w / m_{ql}$ or $m_{ql} / m_w$ vanishes. It seems to indicate that the Higgs boson is a composite of the isodoublet spinor subquark-antisubquark pairs well described by the minimal unified subquark model with either one of subquark masses vanishing. Let us hope that the future LHC experiments will tell us whether the minimal unified subquark model is a viable model of all fundamental particles and forces!

БОЗОН ХІГГСА В МІНІМАЛЬНО УНІФІКОВАНІЙ МОДЕЛІ СУБКВАРКА

В мінімальній субкварковій об’єднаній моделі всіх фундаментальних частинок і сил маса бозона Хіггса \(m_H\) в стандартній моделі електрослабкої взаємодії, за прогнозами, складає близько \(2m_W \sqrt{6/3}\) (де \(m_W\) - маса зарядженого слабкого бозона), так що \(m_H = 131\) ГеВ для \(m_W = 80.4\) ГеВ, до якої експериментальні значення 125-126 ГеВ, нещодавно знайдені в співпраці ATLAS і CMS на LHC, дуже близькі.

Ключові слова: елементарні частинки, бозон Хіггса.
